

Planetary Migration

RENU MALHOTRA
The University of Arizona

Subsequent to planet formation, the gravitational interactions with the gaseous birth disk, with the residual planetesimal disk, and/or with sibling planets are the cause of dramatic orbital migration of planets leading to the final orbital architecture of planetary systems. The basics of these physical mechanisms and related phenomenology will be described, and new results that provide quantitative information about the migration of Jupiter and Saturn in our own solar system will be presented.
